

AI Co-op Career Intelligence Assistant

Ask questions about co-op reports, company advice, interview tips, and student experiences.

Ask a question:

What are the most common tools used in software engineering co-op roles?

Number of sources to use

AI Answer

The context provides some insights into tools and technologies used in various software engineering co-op roles, though it does not list a comprehensive set of the most common tools. From the examples given:

- Front-end development at Samsung involved working with frameworks, tools, and coding standards typical for front-end projects (specific tools not named).
- At Form Athletica, automation scripts were written in Java and Python for testing purposes.
- At SAP, GitHub was used for source control related to UI string management.
- Test automation and framework work were mentioned in a Motorola Solutions co-op role, though specific tools were not named.

Based on this information, common tools in software engineering co-op roles include:

- Programming languages such as Java and Python (for automation and scripting).
- Version control systems like GitHub.
- Frameworks and coding standards relevant to front-end development (specific frameworks not detailed).
- Test automation frameworks (specific tools not detailed).

No explicit list of the most common tools across co-op roles is provided, but these examples suggest that programming languages (Java, Python), version control (GitHub), and automation/testing tools are commonly used.

Summary:

The most common tools mentioned in software engineering co-op roles include programming languages like Java and Python, version control systems such as GitHub, and various frameworks and tools related to front-end development and test automation. However, the context does not provide a detailed or comprehensive list of the most common tools.

Co-op Work Activities:

During my co-op term at Samsung, I have been working primarily as a front-end developer, contributing to the CarePro project. My responsibilities include studying internal documentation, exploring existing codebases, and gradually applying that knowledge to real development tasks. This has allowed me to become familiar with the frameworks, tools, and coding standards used within the organization. One of my key experiences has been participating in workshops and daily team standups. These sessions provided valuable insight into how large-scale software projects are developed and maintained. I was able to observe how product managers define requirements, how UX designers translate those requirements into user-friendly designs, and how de

role is involved with Unity Access (UA), a role-based access system that is used by clients such as the University of Tennessee, Domino's, and Alabama Power. Simply put, this software allows administrators complete control of who has access to buildings, which rooms these people have access to, and when these people have access to them. The structure of the developer teams that work on UA are broken up

into Enterprise/scale, UI Evolution, Core, Support (Non-UA Devs), Krakow (team in Poland), Tools/Automation Team, and Arch & Req & Leadership. The atmosphere of my team (Tool/Automation) is friendly and fairly laid back, with an appropriate push to get your work done that naturally comes with working in two week sprints. My co-workers are happy to lend a hand or explain things to me

th, especially for co-op students. The organization's main "products" and services connected to my role were internal digital tools that support salmon science and policy decision-making. During my term, I was the lead developer for three tools hosted on the DFO-AI Hub: a Web Scraper Chatbot that collects and summarizes web content, a PDF Extraction Tool that converts long technical reports into structured data, and an ML Model Repository that catalogues internal machine learning models and makes them easier to discover and reuse. Together, these internal services help scientists and analysts access information faster, reduce manual data processing, and support evidence-based decisions for Pacific salmon conservation. C)

Co-op Work Activities:

During my co-op term as a Junior Dat

ded. The atmosphere is very collaborative, supportive, and relaxed. My co-workers are very open to communication and provide help when I have trouble understanding things. Furthermore, employees get to work from home every Monday, and can leave early if needed. Overall, the work environment is relaxed and everyone is generally helpful and kind. Co-op Work Activities As a Software Quality Assurance Co-op, my main role is to find and report bugs in Form Athletica's app for both iOS and Android. I also work on the firmware side, such as reviewing the firmware developer's pull requests for bug fixes and feature updates

for the goggles. In addition, I write automation scripts in Java to test the app and have written Python scripts to program a robot that mimics swimming with the goggles. When

File: ReflectiveReport_OSI Maritime Systems_Software Test Engineer_SP25_PART A.docx

a software developed by OSI Maritime Systems for monitoring and controlling ships in bridges (the room where the crew members control their ships). The software can display electric charts, display locations of certain objects, and has many options to control the ship's sensors to aid in maritime navigation. It's a really interesting program to interact with. Co-Op Work Activities The first thing I did as a co-op (after the orientation day) was the onboarding work package, where I got to learn about how the company operates in general and learn about different terminologies and protocols for maritime navigation. This was also when I was first introduced to ECPINS. OSI Maritime's onboarding work package is quite long, even for co-op positions; I took solid three weeks to finish onboarding

or billiards tables meant for employees to use during breaks. The workplace is flexible too, as you're not required to work in a designated spot.

I am on the Language Experience team which coordinates translations for SAP's software products, documentation, and internal content. Our team consists of software developers, project managers, and language quality engineers. Our team develops and maintains a middleware to support the routing of product UI from core development to our translation suppliers. This middleware is meant for internal use only and supports translations across all of SAP. It essentially connects core development's UI strings located in GitHub to our translation editor environment so that external translation suppliers can provide their translations. The middle
